### CS450

### Structure of Higher Level Languages

Lecture 25: SimpleJS

Tiago Cogumbreiro

### My goal with CS450 is to teach you ...

- 1. Fundamental concepts behind most programming languages
  - functional programming, delayed evaluation, control flow and exceptions, object oriented systems, monads, macros, pattern matching, variable scoping, immutable data structures
- 2. A framework to describe language concepts
  - $\lambda$ -calculus and formal systems to specify programming languages
  - functional programming and monads to implement specifications
- 3. A methodology to understand complex systems
  - (formally) specify and implement each programming language feature separately
  - understand a complex system as a combination of smaller simpler systems
  - implement and test features independently

# JavaScript \_\_proto\_\_ deprecated!

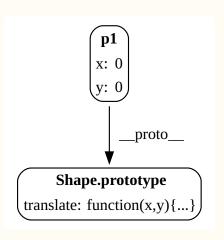

- <u>Direct access to attribute \_\_proto\_\_</u> is <u>discouraged and deprecated!</u>
- However, getting/setting attribute \_\_proto\_\_ is syntactic sugar for <u>GetPrototypeOf</u> and <u>SetPrototypeOf</u> in the JavaScript specification.
- We are using <u>\_\_proto\_\_</u> mainly because we are following the Essence of JavaScript.
- Prototypes can be updated dynamically due to mutation

## JavaScript function objects

We can use field prototype to declare the prototype of a given class. We can also use field prototype to add methods to an object. Operation new assigns Shape.prototype to p1.\_\_proto\_\_.

```
function Shape(x, y) {
  this.x = x;
  this.y = y;
// This way we bind the method once
Shape.prototype.translate = function (x, y) {
   this.x += x;
   this.y += y;
p1 = new Shape(0, 1);
p1.translate(10, 20);
console.assert(p1.x = 10);
console.assert(p1.y = 21);
```

### Desugaring object inheritance

```
var Shape = (obj, x, y) \Rightarrow \{ // Shape's constructor \}
 obj.x = x;
 obj.y = y;
  return obj
Shape.prototype = {} // Shape extends Object
Shape.prototype.translate = function(x, y) \{ // Also add method translate \}
 this.x += x;
 this.y += y;
p1 = Shape({"__proto__": Shape.prototype}, 0, 1); // When creating, init prototype
p1.translate(10, 20);
console.assert(p1.x = 10);
console.assert(p1.y = 21);
```

### Desugaring class creation

#### Version 3

```
class Shape {
  constructor(x, y) {
    this.x = x;
    this.y = y;
  }
  translate(x, y) {
    this.x += x;
    this.y += y;
  }
}
p1 = new Shape(0, 1);
```

#### Version 2

```
function Shape(x, y) {
   this.x = x;
   this.y = y;
}
Shape.prototype.translate =
     function (x, y) {
   this.x += x;
   this.y += y;
}
p1 = new Shape(0, 1);
```

#### Version 1

```
Shape = (obj, x, y) ⇒ {
  obj.x = x;
  obj.y = y;
  return obj
}
Shape.prototype = {}
Shape.prototype.translate =
     function (x, y) {
  this.x += x;
  this.y += y;
}
p1 = Shape(
  {"__proto__": Shape.prototype},
  0, 1);
```

### Inheritance desugaring

```
class Rectangle extends Shape {
  constructor(width, height) {
    super(0, 0);
    this.width = width;
    this.height = height;
  }
}
var r1 = new Rectangle(10, 20);
```

```
function Rectangle(width, height)
  Shape.call(this, 0, 0);
  this.width = width;
  this.height = height;
}
Rectangle.prototype =
    {"__proto__": Shape.prototype]
var r1 = new Rectangle(10, 20);
```

### Today we will...

- Revise JavaScript's object system
- Introduce SimpleJS: S-Expression-based syntax and simpler JavaScript rules
- Introduce LambdaJS:  $\lambda$ -calculus + references + immutable objects
- Introduce translation from SimpleJS into LambdaJS

#### Why are we learning all SimpleJS and LambdaJS?

- You already know  $\lambda$ -calculus with references (heap)
- You already know how objects work (ie, a map with a lookup that work like frames and environments)
- I want to teach you the fundamentals of JavaScript by building it on top of concepts that you already know!
- I can introduce another kind of specifying the semantics of a system, by translating it into another system (<u>denotational semantics</u>)

  UMass
  Boston

#### Object prototypes

A.\_\_proto\_\_ = B links A object to B, if a field f is not available in A, then it is looked up in B (which works recursively until finding undefined).

```
a = {"x": 10, "y": 20}
b = {"x": 30, "z": 90, "__proto__": a}
b {x: 30, z: 90, *y: 20}
```

#### Functions are constructors

If we call a function A with new, then A is called as the constructor of a new object.

```
function C(x, y) { this.x = x; this.y = y }
c = new C(10, 20)
c {x: 10, y: 20}
```

#### Constructor's prototype

If A is a function, then A.prototype becomes the \_\_proto\_\_ of every object created using A with new.

```
C.prototype = {"foo": true, "bar": 100}
d = new C(10, 20)
d {x: 10, y: 20, *foo: true, *bar 100}
```

# SimpleJS

## Introducing SimpleJS

- SimpleJS is just a simplification of JavaScript with fewer corner case, which is easier to learn.
- SimpleJS was created by your instructor for CS450 (yet close to what you have in The Essence of JavaScript)
- SimpleJS has a formal syntax (below) and also an S-expression syntax (hw8-util.rkt)
- Today we will **formally** describe SimpleJS in terms of how we can represent it in LambdaJS (defined in The Essence of JavaScript).

$$e ::= x \mid \mathtt{let} \ x = e \ \mathtt{in} \ e \mid x.y \mid x.y := e \mid x.y(e \cdots) \ \mid \mathtt{function}(x \cdots) \{e\} \mid \mathtt{new} \ e(e \cdots) \ \mid \mathtt{class} \ \mathtt{extends} \ e \ \{\mathtt{constructor}(x \cdots) \{e\} \ m \cdots \}$$

$$m ::= x(x \cdots)\{e\}$$

## Writing Shape in SimpleJS

JavaScript

```
function Shape(x, y) {
    this.x = x;
    this.y = y;
let p = new Shape(10, 20);
Shape.prototype.translate =
    function(x, y) {
      this.x = this.x + x;
      this.y = this.y + y;
p.translate(1,2);
return p;
```

#### SimpleJS

```
(let Shape
  (function (x y)
    (begin (set! this.x x)
           (set! this.y y)))
  (let p (new Shape 10 20)
    (let Shape-proto Shape.prototype
      (begin
        (set! Shape-proto.translate
          (function (x y)
            (begin
              (set! this.x (! + this.x x))
              (set! this.y (! + this.y y)))))
        (p.translate 1 2)
        p))))
                                            Boston
```

#### JavaScript

#### SimpleJS

JavaScript

SimpleJS

What are the possible problems of this form of inheritance?

JavaScript

SimpleJS

What are the possible problems of this form of inheritance?

How can we add a new method to Rectangle?

With the highlighted pattern we can safely mutate Rectangle.prototype. This is the same as Rectangle.prototype = {'\_proto\_': Shape.prototype }, but we have no syntax for such a pattern in SimpleJS.

#### JavaScript

```
function Rectangle(width, height) {
  this.x = 0;
  this.y = 0;
  this.width = width;
  this.height = height;
let p = function () {}
p.prototype = Shape.prototype;
Rectangle.prototype = new p();
let r1 = new Rectangle(10, 20);
return r1;
```

#### SimpleJS

# LambdaJS

### LambdaJS

Think Racket without define, without macros, with objects, and heap operations.

#### Expressions

$$e ::= v \mid x \mid \lambda x.e \mid e(e) \mid \{s \colon e\} \mid e[e] \mid e[e] \leftarrow e \mid \mathtt{alloc} \ e \mid e := e$$

# Concrete LambdaJS S-expression syntax

Formal syntax	S-expression
$\lambda x.e$	(lambda (x) e)
$e_1(e_2)$	(e1 e2)
$\{\texttt{"foo"}: 1+2, \texttt{"bar"}: x\}$	(object ["foo" (+ 1 2)] ["bar" x])
$o[ exttt{"foo"}]$	(get-field o "foo")
$\verb"alloc" \{\}$	<pre>(alloc (object))</pre>
$x := \{\}$	<pre>(set! x (object))</pre>
x:=1;x	(begin (set! $x$ 1) $x$ )
$let\; x\; =\; 10\;in\; x+4$	(let ([x 10]) (+ x 4))

In Racket you can actually allocate a reference with (box e), which is equivalent to LambdaJS(alloc e), and update the contents of that reference with (set-box! b e) which is equivalent to LambdaJS (set! e).

# Translating SimpleJS into LambdaJS

 $\bigcirc$ 

## Translating SimpleJS into LambdaJS

- 1. A SimpleJS object is represented as a reference to an immutable LambdaJS object
- 2. A SimpleJS function is represented as an object with two fields: (a) a lambda-function that represents the code, a prototype field which points to an empty SimpleJS object
- 3. Create an object with new expects a SimpleJS function as argument and must create a new object, initialize its prototype, and call the constructor function (see point 2)
- 4. Method invocation corresponds to accessing a SimpleJS function and passing the implicit this object to it (see 2)

#### Objectives of the translation

- Explicit this
- Functions are not objects: convert function into an object+lambda
- Explicit memory manipulation
- No method calls: use function calls

## Translating a function

#### JavaScript

```
function Shape(x, y) {
  this.x = x;
  this.y = y;
};
```

#### Step 1: only objects and lambdas

```
Shape = {
    '$code': (obj, x, y) ⇒ {
      obj.x = x;
      obj.y = y;
    },
    'prototype' = {}
};
```

### Translating a function

#### JavaScript

```
function Shape(x, y) {
  this.x = x;
  this.y = y;
};
```

Step 1: only objects and lambdas

```
Shape = {
    '$code': (obj, x, y) ⇒ {
      obj.x = x;
      obj.y = y;
    },
    'prototype' = {}
};
```

#### Step 2: explicit references

```
Shape = alloc {'$code': (this, x, y) \Rightarrow {
    this = (deref this)["x"] \leftarrow x; // In LambdaJS we have to replace the whole object
    this = (deref this)["y"] \leftarrow y;},
    'prototype': alloc {}};
```

**Boston** 

## Translating new

JavaScript

```
p1 = new Shape(0, 1);
```

Step 1: only objects and lambdas; no implicit this

```
p1 = {"__proto__": Shape.prototype};
Shape["$code"](p1, 0, 1);
```

### Translating new

JavaScript

```
p1 = new Shape(0, 1);
```

Step 1: only objects and lambdas; no implicit this

```
p1 = {"__proto__": Shape.prototype};
Shape["$code"](p1, 0, 1);
```

Step 2: explicit references

```
p1 = alloc {"__proto__": (deref Shape)["prototype"]}};
(deref Shape)["$code"](p1, 0, 1);
```

### Translating method invocation

JavaScript

```
p1.translate(10, 20);
```

Step 1: only objects and lambdas; no implicit this

```
m = p1["translate"];  // get object method
m["$code"](p1, 10, 20); // get code for method
```

### Translating method invocation

JavaScript

```
p1.translate(10, 20);
```

Step 1: only objects and lambdas; no implicit this

```
m = p1["translate"];  // get object method
m["$code"](p1, 10, 20); // get code for method
```

Step 2: explicit references

Formally

```
m = (deref p1)["translate"];
(deref m)["$code"](p1, 10, 20);
```

SimpleJS

### Translating SimpleJS into LambdaJS

Before

```
Shape.prototype.translate = function(x, y)
    this.x += x; this.y += y;
};
p1 = new Shape(0, 1);
p1.translate(10, 20);
```

After

```
// 1. Function declaration
Shape = alloc {
  "code": (this, x, y) \Rightarrow \{ \dots \},
  "prototype" = alloc {}};
p = (deref Shape)["prototype"];
(deref p)["translate"] = alloc {
  "code": (this, x, y) \Rightarrow { ... }
  "prototype": alloc {}};
// 2. new
p1 = alloc {"__proto__":
           (deref Shape)["prototype"]};
(deref Shape)["$code"](p1, 0, 1);
// 3. method call
f = (deref p1)["translate"]:
                                     UMass
(deref f)["$code"](p1, 10, 20);
                                     Boston
```

# Translation function

### Translation function

- Field lookup
- Field update
- Function declaration
- The new keyword
- Method call
- Class declaration

# Field lookup

### Field lookup

$$J[x.y] = (get-field (deref x) "y")$$

SimpleJS

 $\lambda$ -JS

this.x

(get-field (deref this) "x")

# Field update

## Field update

In JavaScript, assigning an expression e into a field, returns the evaluation of e. However, in LambdaJS assignment returns the reference being mutated.

```
J\llbracket x.y := e 
rbracket = (let ([\underline{data} \ J\llbracket e 
rbracket]) (begin (set! \underline{x} (set-field (deref \underline{x}) "y" data)) data))
```

SimpleJS

```
(set! this.x x)
```

 $\lambda$ -JS

```
(let [(data x)]
  (begin
      (set! this
            (update-field (deref this) "x" data)))
      data)))
```

### Free variables and bound variables

#### SimpleJS

 $\lambda$ -JS

```
(set! data.x 10)
```

What happened here?

### Free variables and bound variables

```
\mathbf{J}\llbracket x.y := e 
rbracket = (\operatorname{let} ([\underline{data} \ \mathbf{J}\llbracket e 
rbracket]) (\operatorname{begin} (\operatorname{set!} \underline{x} (\operatorname{set-field} (\operatorname{deref} \underline{x}) "y" \operatorname{data})) \operatorname{data}))
```

#### SimpleJS

```
(set! data.x 10)
```

 $\lambda$ -JS

#### What happened here?

- 1. Variable data is used in the generated code
- 2. We must ensure that data is not captured (free) in the generated code!

### Quiz

What problem occurs when generating code?

(One sentence is enough.)

# Function declaration

### Function declaration

Field prototype can be accessed by the user, so we declare it as a reference. Field \$code does not actually exist in JavaScript, so we prefix it with a dollar sign (\$) to visually distinguish artifacts of the translation.

```
\mathbf{J}\llbracket \mathtt{function}(x\cdots) \ \{e\} \rrbracket = (\mathtt{alloc} \ (\mathtt{object} \ [\texttt{"$code"} \ (\mathtt{lambda} \ (\underline{this},\underline{x}\cdots) \ \mathbf{J}\llbracket e \rrbracket)][\texttt{"prototype"} \ (\mathtt{alloc} \ (\mathtt{object} \ )))]))
```

#### SimpleJS

```
(function (x y)
  (begin
        (set! this.x x)
        (set! this.y y)))
```

#### $\lambda$ -JS

# The new keyword

## The new keyword

```
\mathbf{J}\llbracket \mathbf{new}\ e_f(e\cdots) 
rbracket = 0
                                              (let ([\underline{c} (deref J[[e_f])])
          (\text{let }([\underline{o} \ (\text{alloc } (\text{object } [\text{"\$proto"}(\text{get-field } \underline{c} \ \text{"prototype"})]))])
                          (begin ((get-field \underline{c} "$code") \underline{o} J[[e]] \cdots) \underline{o})))
SimpleJS
                                  \lambda-IS
 (new Shape 0 1)
                                   (let [(ctor (deref Shape))
                                            (o (alloc (object "$proto" (get-field ctor "prototype"))))]
                                      (begin
                                         ((get-field ctor "$code") o 0 1)
                                         0))
```

# Method invocation

### Method invocation

```
(p1.translate 10 20)
```

```
((get-field
  (deref (get-field (deref p1) "translate"))
  "$code")
  p1 10 20)
;; In Racket pseudo code
(define p1:obj (deref p1)) ; 1. get obj from ref
(define translated:m (get-field p1:obj "translate")) ; 2. get fiel
(define translated:o (deref translated:m)) ; 3. get object from re
(define translated:f (get-field translated:o "$code") ; 4. get fun
(translated:f p1 10 20) ; 5. call fun pass this (p1)
```

### Function call

What is the value of this when calling a function outside of new/method-call? this is initialized to the global variable window.

We will not be implementing function calls in Homework Assignment 8.

```
\mathbf{J}\llbracket e_f(e\cdots)
rbracket = \\ ig( (	exttt{get-field (deref } \mathbf{J}\llbracket e_f 
rbracket) 	exttt{"$$ $\mathbf{vindow}$ } \mathbf{J}\llbracket e\cdots 
rbracket
```

#### Example 1

```
class Foo {
  constructor() { this.x = 0; }
  bar() { this.x++; }
}
var foo = new Foo();
foo["bar"](); // foo.bar();
// Caveat: foo.bar() ≠ (foo.bar)()
```

#### Example 2

```
class Foo {
  constructor() { this.x = 0; }
  bar() { this.x++; }
}
var foo = new Foo();
var bar = foo["bar"];
bar(); // TypeError: this is undefined
```

# Class declaration

### Class declaration

To allow dynamically dispatching to X's methods, the first four lines instantiate X without calling its constructor. This way, we can safely mutate the  ${\bf cls}$ 's prototype without affecting X and any changes to X are visible to  ${\bf cls}$  via lookup.

```
\mathbb{C}[[class extends X \{body\}]] =
                        let parent = \mathbb{C}[X] in
                 let parent' = function (){} in
             parent'.prototype := parent.prototype
                     let proto = new parent' in
               let cls = function (x\cdots)\{e_c\} in
                      cls.prototype := proto;
            	extstyle{\mathsf{proto.m}} := 	extstyle{\mathsf{function}}(y\cdots)\{e_m\}; \cdots
                                    cls
where body = \mathtt{constructor}(x \cdots) \{e_c\} \ m(y \cdots) \{e_m\} \cdots
```
