### CS450

#### Structure of Higher Level Languages

Lecture 09: Dynamically-created funcs, storing funcs in lists, currying

Tiago Cogumbreiro

# Module 3:

Lazy evaluation

#### Module 3

#### Lazy evaluation

- Using functions to delay computation
- Lazy evaluation as a form of controlling execution
- Lazy evaluations as data-structures
- Functional patterns applied to delayed

# Delayed evaluation

### Recall the evaluation order

#### Function application

The evaluation of function application can be called *eager* 

 Evaluating a function application, first evaluates each argument before evaluating the body of the function.

#### Condition

The evaluation of **cond** can be called **lazy**, in the sense that a branch of **cond** is only evaluated when its guard yields true (and only the one branch is evaluated).

### How to encode an if-then-else?

```
(define (factorial n)
  (cond \Gamma (= n 0) 1]
         [else (* n (factorial (- n 1)))]))
Example
 (define (if b then-branch else-branch)
   (cond [b then-branch] [else else-branch]))
 (define (factorial n)
  (if (= n 0) 1 (* n (factorial (- n 1)))))
 (factorial 10)
```

What is wrong with this implementation?

### How to encode an if-then-else?

```
(define (factorial n)
  (cond \Gamma (= n 0) 1]
         [else (* n (factorial (- n 1)))]))
Example
 (define (if b then-branch else-branch)
   (cond [b then-branch] [else else-branch]))
 (define (factorial n)
  (if (= n 0) 1 (* n (factorial (- n 1)))))
 (factorial 10)
```

What is wrong with this implementation? Why (factorial 10) does not terminate?

# Our implementation of if is too eager

Because our if is a function, applying evaluates the then-branch and the else-branch before choosing what to return.

Which, means our factorial no longer has a base case, and, therefore, it does not terminate.

```
= (factorial 0)
= (if (= 0 0) 1 (* 0 (factorial (- 0 1))))
= (if #t 1 (* 0 (factorial (- 0 1))))
= (if #t 1 (* 0 (factorial -1)))
= (if #t 1 (* 0 (if (= 0 -1) (= 0 -1) (* -1 (factorial (- -1 1))))))
= ...
```

Any idea how we can work around this limitation?

# Using lambdas to delay computation

We can use a zero-argument lambda to hold each branch, as a lambda delays computation!

```
(define (if b then-branch else-branch)
  (cond [b (then-branch)] [else (else-branch)]))

(define (factorial n)
  (if (= n 0) (lambda () 1) (lambda () (* n (factorial (- n 1))))))

(factorial 10)
```

### Thunks: zero-argument functions

The pattern of using zero-argument functions to delay evaluation is called a **thunk**. You can use thunk as a verb which is a synonym of delaying evaluation.

- (lambda () e) delays expression e
- (e) evaluates thunk e and calls that thunk

# Using thunk

Racket offers (thunk e) as a short-hand notation for (lambda () e); both notations are equivalent.

```
(define (if b then-branch else-branch)
  (cond [b (then-branch)] [else (else-branch)]))

(define (factorial n)
  (if (= n 0) (thunk 1) (thunk (* n (factorial (- n 1))))))

(factorial 10)
```

# Functional patterns: promises

### Repeated delayed computation

In functional programming, there are cases where you have an intertwined pipeline of functions where a thunk might be carried around. Since, we aim at side-effect free programming models, it is wasteful to compute a thunk multiple times, when at most one would do.

#### Example

It might not possible to know, at the function-level, if thunk was already called, as it depends on the caller and, in this case, on call-back as well.

### Promises: memoize delayed computation

- (delay e) delays the evaluation of an expression (yielding a thunk)
- (force e) caches the result of evaluating e, so that multiple applications of that thunk return the result.

#### Did you know?

- Memoization: optimization technique that caches the result of an expensive function and returns the cached result
- Haskell does not share the same evaluation model as we have in Racket. Instead, all
  expressions of the language are lazily evaluate.
- The idea of memoized delayed evaluation provides an elegant way to parallelize code. The concept is usually known as a *future*.
- The idea of memoized delayed evaluation (promises) is also very important in asynchronous code (networking, and GUI), eg in JavaScript, in Python

# Example: delay/force

#### Thunks

#### Promises

#### Promises versus thunks

#### Accessor

- Promises: must call function force
- Thunks: call the object itself

#### **Evaluation** count

- (force p) evaluates the promise at most once; subsequent calls are cached
- (thnk) calling a thunk evaluates its contents each and every time

# Implementing promises

### Implementing promises: state

Promises are usually implemented with mutable references. Can we get away with implementing promises without using mutation?

#### A promise has two states:

- 1. when the thunk has not been run yet
- 2. when the thunk has been run at least once

#### A promise must hold:

- the thunk we want to cache
- the empty/full status

We need to separate the operations that mutate the state, from the ones that query the state.

## Implementing promises: operations

Function (force c) can be though of a few smaller operations:

- 1. checking if the promise is empty
- 2. if the promise is empty, update the promise state to full and store the result of the thunk
- 3. if the promise is full, does nothing to the promise state, and returns the cached result

Let us separate the operations that change the state from the one that return the value.

- Function (promise-sync p) returns a new promise state. When the promise is empty, it computes the thunk and stores it in a full promise. When the promise is full, it just returns the promise given.
- Function (promise-get p) can only be called when the promise is full and returns the result of the promise.

### Immutable promise implementation

```
(struct promise (empty? result))
(define (make-promise thunk) (promise #t thunk))
(define (promise-run w)
   (define th (promise-result w))
   (th))
(define (promise-get p)
   (cond [(promise-empty? p) (error "promise: call (promise-sync p) first.")]
        [else (promise-result p)]))
(define (promise-sync p)
   (cond [(not (promise-empty? p)) p]
        [else (promise #t (promise-run p))]))
```

## Example of immutable promises

Immutable Promises

Standard promises

# Streams

#### Stream

A stream is an infinite sequence of values.

**Did you know?** The concept of streams is also used in:

- Reactive programming (eg, a stream of GUI events for Android development)
- Stream processing for digital signal processing (eg, image/video codecs with the language StreamIt)
- Unix pipes (eg, a pipeline of Unix process producing and consuming a stream of data)
- See also Microsoft LINQ and Java 8 streams

#### Streams in Racket

A stream can be recursively defined as a a pair holds a value and another stream stream = (cons some-value (thunk stream))

```
Powers of two

(cons 1 (thunk (cons 2 (thunk (cons 4 (thunk ...))))))

Visually

1 2 4 ...

Using streams
```

## Revisiting our example with helper functions

```
; Retrieves the current value of the stream
(define (stream-get stream) (car stream))
; Retrieves the thunk and evaluates it, returning a thunk
(define (stream-next stream) ((cdr stream)))

(check-equal? 1 (stream-get (powers-of-two)))
(check-equal? 2 (stream-get (stream-next (powers-of-two))))
(check-equal? 4 (stream-get (stream-next (powers-of-two)))))
```

# Count elements in stream

### Programming with streams

Let us write a function that given a stream and a predicate, counts how many times a predicate holds true until it becomes false.

#### Spec

```
(check-equal? 3 (count-until (powers-of-two) (lambda (x) (< x 8)))) (check-equal? 0 (count-until (powers-of-two) (lambda (x) (\leq x 0)))) (check-equal? 3 (count-until (powers-of-two) (curryr < 8))); Reverse Currying (check-equal? 0 (count-until (powers-of-two) (curryr \leq 0))); Reverse Currying
```

### Programming with streams

Let us write a function that given a stream and a predicate, counts how many times a predicate holds true until it becomes false.

#### Spec

```
(check-equal? 3 (count-until (powers-of-two) (lambda (x) (< x 8))))</pre>
(check-equal? 0 (count-until (powers-of-two) (lambda (x) (\leq x 0)))
(check-equal? 3 (count-until (powers-of-two) (curryr < 8))) ; Reverse Currying
(check-equal? 0 (count-until (powers-of-two) (curryr \leq 0))); Reverse Currying
```

#### Solution

```
(define (count-until stream pred)
  (define (count-until-iter s count)
    (cond [(pred (stream-get s)) (count-until-iter (stream-next s) (+ count 1))]
          [else count]))
  (count-until-iter stream 0))
                                                                                    Boston
```

# Implementing powers of two

## Example: powers of two

Implement the stream powers-of-two

## Example: powers of two

Implement the stream powers-of-two

#### Solution

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
     (cons n (thunk (powers-of-two-iter (* 2 n)))))
     (powers-of-two-iter 1))
```

# The stream of constants

### Example: constant

Implement a function const that given a value it returns a stream that always yields that value.

```
(check-equal? 20 (stream-get (const 20))
(check-equal? 20 (stream-get (stream-next (const 20)))
(check-equal? 20 (stream-get (stream-next (stream-next (const 20)))))
```

### Example: constant

Implement a function const that given a value it returns a stream that always yields that value.

```
(check-equal? 20 (stream-get (const 20))
(check-equal? 20 (stream-get (stream-next (const 20)))
(check-equal? 20 (stream-get (stream-next (stream-next (const 20)))))
```

#### Solution

## Common mistakes (1)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
     (cons n (powers-of-two-iter (* 2 n))))
  (powers-of-two-iter))
```

## Common mistakes (1)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
     (cons n (powers-of-two-iter (* 2 n))))
  (powers-of-two-iter))
```

Forgot to guard recursion behind a thunk; endless loop.

# Common mistakes (2)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
     (cons n (thunk (powers-of-two-iter (* 2 n)))))
  powers-of-two-iter 1)
```

# Common mistakes (2)

```
(define (powers-of-two)
  (define (powers-of-two-iter n)
     (cons n (thunk (powers-of-two-iter (* 2 n)))))
  powers-of-two-iter 1)
```

Forgot the parenthesis/forgot to call the constructor; does not return a stream.

# The stream of natural numbers

#### Streams in Racket

A stream can be recursively defined as a a pair holds a value and another stream stream = (cons some-value (thunk stream))

```
A stream of natural numbers

(cons 0 (thunk (cons 1 (thunk (cons 2 (thunk ...)))))

Visually

0 1 2 3 4 5 6 ...

Using streams

(check-equal? 0 (stream-get (naturals)))
 (check-equal? 1 (stream-get (stream-next (naturals))))
```

(check-equal? 2 (stream-get (stream-next (stream-next (naturals)))))

### Natural numbers

Implement the stream of non-negative integers

```
0 1 2 3 4 5 6 7 ...
Spec
```

```
#lang racket
(require rackunit)

(define s0 (naturals))
(check-equal? 0 (stream-get s0))

(define s1 (stream-next s0))
(check-equal? 1 (stream-get s1))

(define s2 (stream-next s1))
(check-equal? 2 (stream-get s2))
```

### Natural numbers

Implement the stream of non-negative integers

```
0 1 2 3 4 5 6 7 ...
Spec
```

```
#lang racket
(require rackunit)
(define s0 (naturals))
(check-equal? 0 (stream-get s0))
(define s1 (stream-next s0))
(check-equal? 1 (stream-get s1))
(define s2 (stream-next s1))
(check-equal? 2 (stream-get s2))
```

#### Solution
